# Incrementalizing $\lambda$ -Calculi by Static Differentiation

Problem: Incremental computation

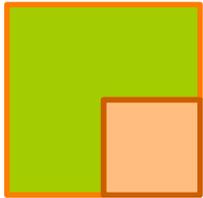

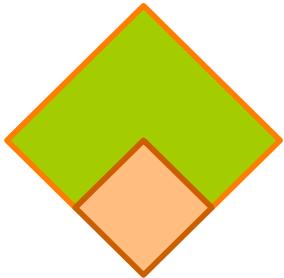

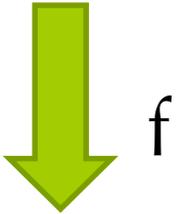

- ✓ Support for a language with first-class functions!
- ✓ Mechanized proof in Agda
- ✓ Implementation in Scala
- ✓ Performance case-study

 $X_1$  $Y_1$  $X_2$  $Y_2$

 $X_1$  $Y_1$  $X_2$  $Y_2$

 $x_1$  $y_1$ 

**f invoked  
again! ☹️**

 $x_2$  $y_2$

# General examples

- Task: Compute statistics on a database of all citizens of France
  - Each time something changes, update statistics
  - Changes are small
  - Can update results without recomputation?
- Variant: statistics on Twitter timelines
  - And keep these statistics up-to-date in real-time.

# Examples

- Task: typecheck & compile a program, or a proof script (say, in Coq)
  - Change: Update a basic definition of the program
  - Changes are still “small”
  - Can update results without recomputation?

 $x_1$  $y_1$  $x_2$  $y_2$

# Running example

- Sum numbers from a collection
- **Base** input collection  $x_1$ :  $\{\{1, 1, 2, 3, 4\}\}$
- **Updated** input collection  $x_2$ :  $\{\{1, 2, 3, 4, 5\}\}$
- The collection is a bag (that is, a multiset)
  - Like in sequences, elements can be repeated
  - Like in sets, order is irrelevant

# Example

f coll = fold (+) 0 coll

y = f x

$x_1 = \{\{1, 1, 2, 3, 4\}\}$

base input

$y_1 = 1 + 1 + 2 + 3 + 4 = 11$

base output

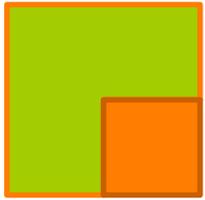

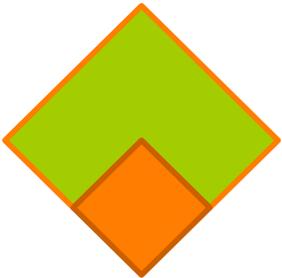

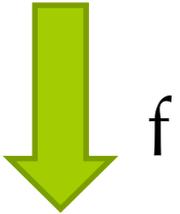

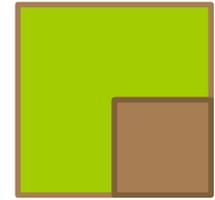

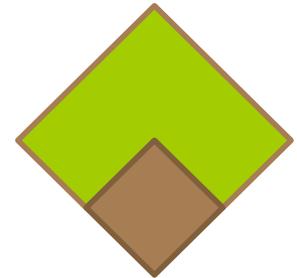

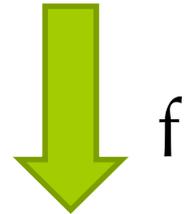

$x_2 = \{\{1, 2, 3, 4, 5\}\}$

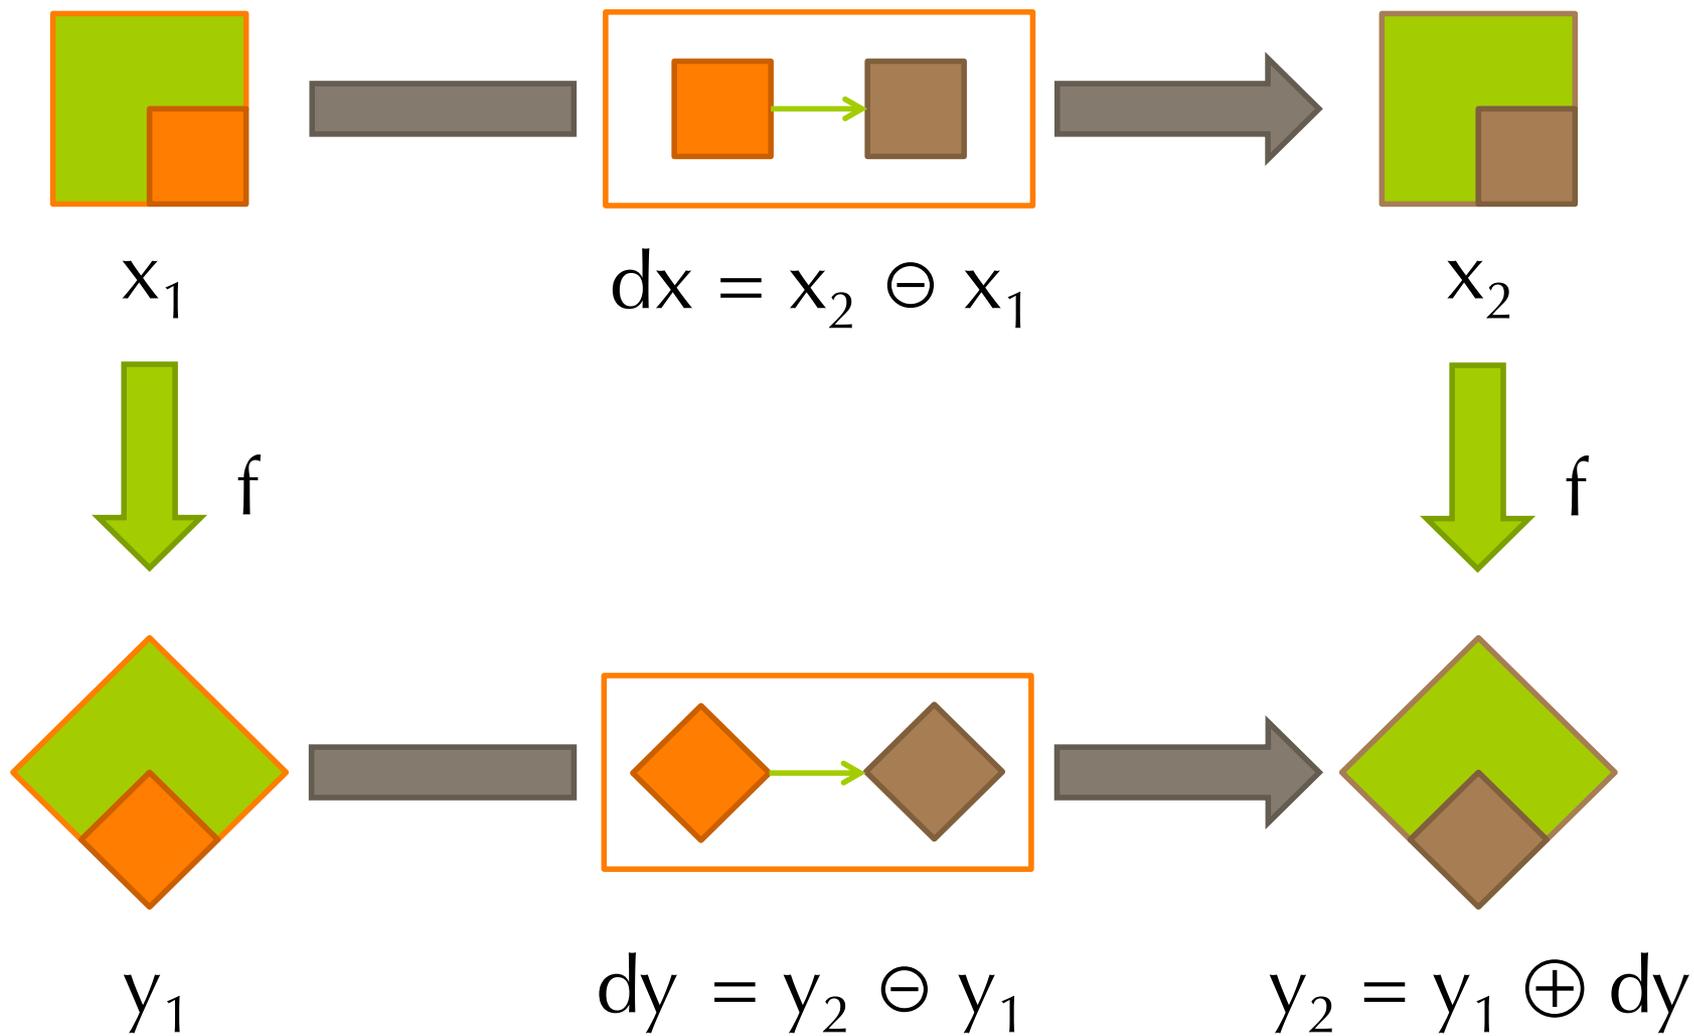

upd. input

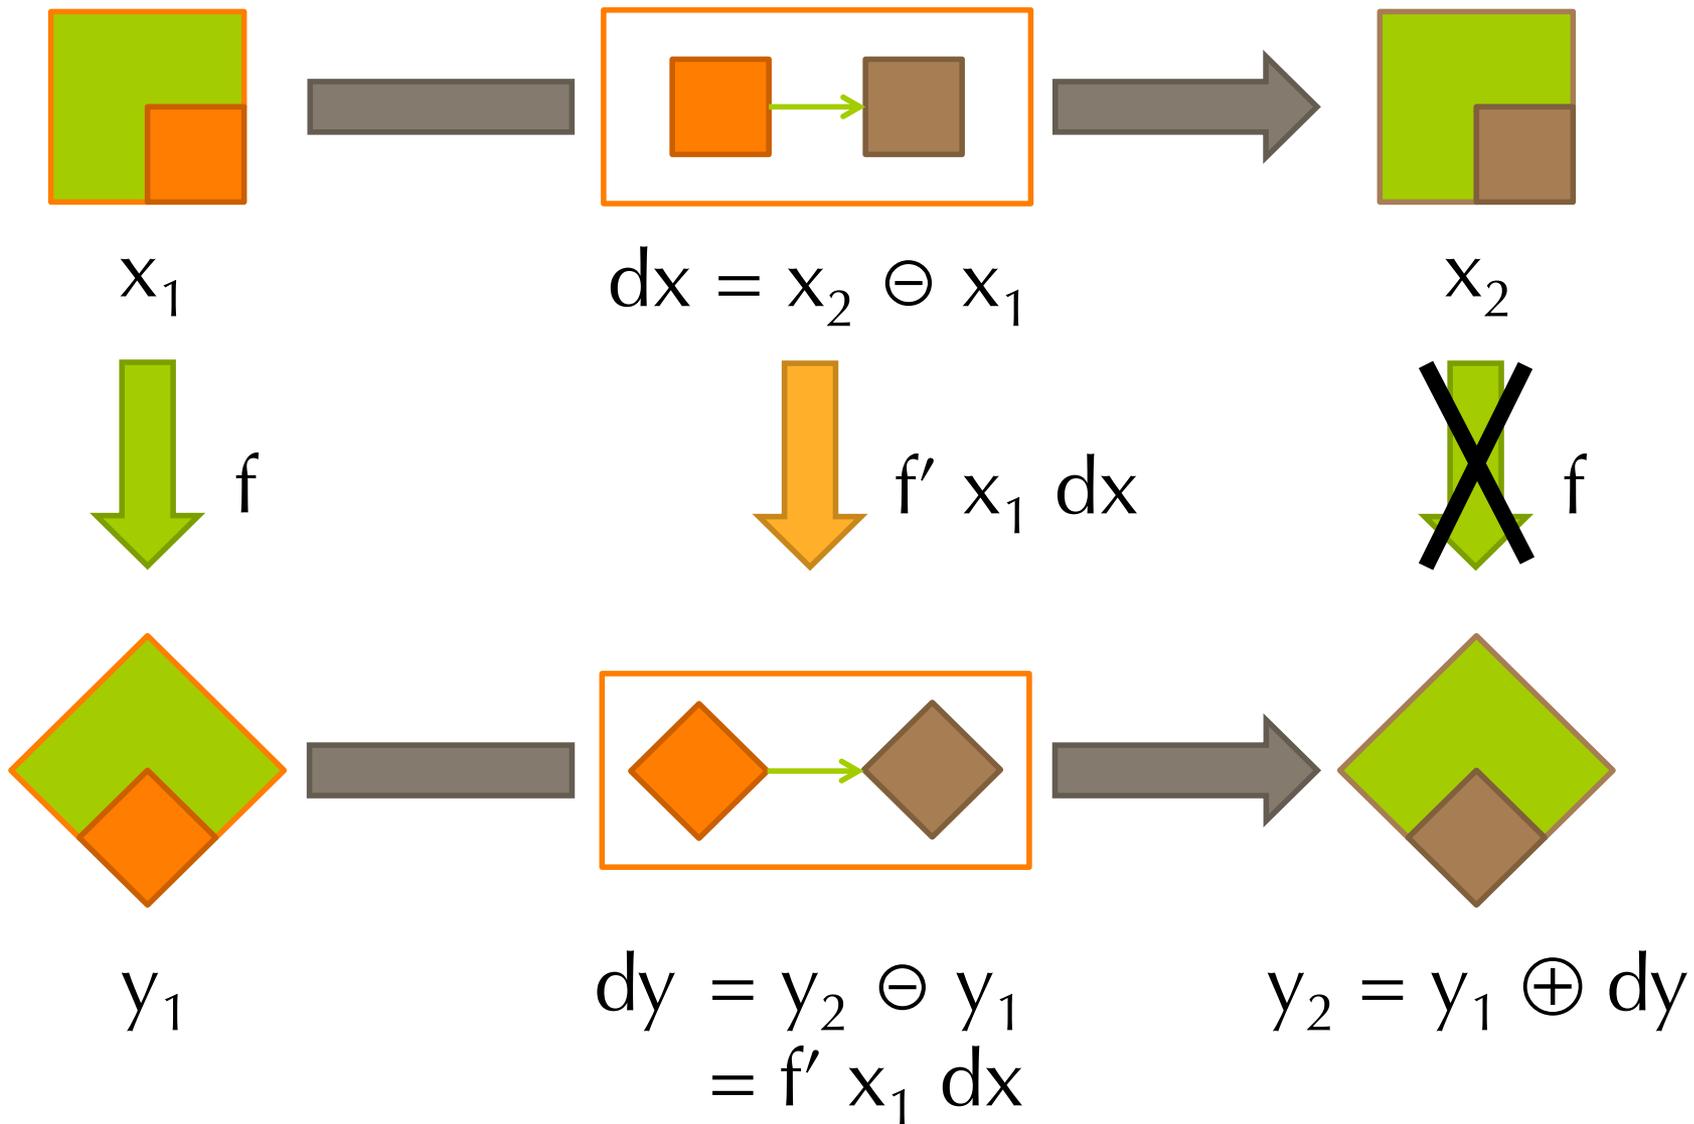

$y_2 = 1 + 2 + 3 + 4 + 5$

upd. output

$= 15 = s_1 - 1 + 5$

 $x_1$  $y_1$  $x_2$  $y_2$

# Example

$$f \text{ coll} = \text{fold } (+) \ 0 \ \text{coll}$$

$$y = f \ x$$

$$x_1 = \{\{1, 1, 2, 3, 4\}\}$$

$$y_1 = 11$$

$$x_2 = \{\{1, 2, 3, 4, 5\}\}$$

$$dx = \{\{1, 2, 3, 4, \mathbf{5}\}\} \ominus \{\{\mathbf{1}, 1, 2, 3, 4\}\} = \{\{5, \underline{1}\}\}$$

$$\begin{aligned} y_2 &= x_1 \oplus f' \ x_1 \ dx = 11 \oplus (-1 + 5) \\ &= 15 \end{aligned}$$

# Derivatives

$f'$  is the *derivative* of  $f$  if

- input: base input  $x_1$ ; a change  $dx$  valid for  $x$
- output: change  $dy$  valid for *base output* ( $f x$ )
- correctness:

$$(f x_1) \oplus (f' x_1 dx) = f (x_1 \oplus dx)$$

- Notation: application binds tighter than anything

$$f x_1 \oplus f' x_1 dx = f (x_1 \oplus dx)$$

# Using derivatives: idea

First, base computation:

$$y_1 = f(x_1)$$

Later, incremental computation “algorithm”:

$$y_2 = y_1 \oplus dy = y_1 \oplus f'(x_1) dx$$

instead of

$$y_2 = f(x_1 \oplus dx)$$

# Setting

- An algebraic theory of change structures for functions
  - To specify and reason about the problem
  - Using dependent types!
- A code transformation *Derive* produces derivatives of programs
  - simply-typed  $\lambda$ -calculus **programs** (STLC), parameterized by a plugin for constants and base types

# Proof strategy

We decompose our transformation into 2 phases

- *non-standard denotational semantics*
  - simply-typed  $\lambda$ -calculus **programs** (STLC)  $\rightarrow$  type theory **functions** (Agda)
- erasure to extract STLC programs
  - we should have used *modified realizability*?
- Proof each phase correct

# Signature of change structures

## Types

- (C1)  $V$  type *base type*
- (C2)  $\Delta x$  type  $\forall x : V$  *change types*

## Operations

- (C3)  $x_1 \oplus dx : V$   $\forall dx : \Delta x_1$  *update*
- (C4)  $x_2 \ominus x_1 : \Delta x_1$  *difference*

## Algebraic equations

- (C5)  $x_1 \oplus (x_2 \ominus x_1) = x_2$  *cancellation*

# Change structure for naturals

Let's define a change structure such that:

$$x \oplus dx = x + dx$$

$$x_2 \ominus x_1 = x_2 - x_1$$

like in the examples in the beginning of the talk.

# Change structure for naturals

So we define:

(C1) *base type*:  $\mathbb{N}$

(C2) *change types*:

$$\Delta x = \{ dx \in \mathbb{Z} \mid x + dx \geq 0 \}$$

$$(C3) \quad x_1 \oplus dx = x_1 + dx : \mathbb{N}$$

$$(C4) \quad x_2 \ominus x_1 = x_2 - x_1 : \Delta x_1$$

$$(C5) \quad x_1 \oplus (x_2 \ominus x_1) = x_1 + (x_2 - x_1) = x_2$$

# Example derivatives

Remember:  $y_2 = y_1 \oplus dy = y_1 \oplus f' x_1 dx$

$$\text{id } x = x$$

$$\text{id}' x dx = dx$$

$$f x = x + 5$$

$$f' x dx = dx$$

# Change structures

- **Algebraic** theory of changes (ToC)
  - for **equational reasoning**
- Change types  $\neq$  base type
  - (unlike calculus in math, Koch [2010], Gluche et al. [1997] in CS)
- ToC is about mathematical functions (in type theory), not programs
- ToC extended to programs through denotational semantics

# An equivalence of changes?

- There can be multiple changes which “do the same thing”
- Example:  
 $\{\{1,2,3,4,5\}\} \ominus \{\{1,1,2,3,4\}\}$  can be represented by  $\{\{5, \underline{1}\}\}$  or by “change **1** through **+4**”.

# Change equivalence (d.o.e.)

Take  $x \in V$ ,  $dx_1, dx_2 \in \Delta x$   
 $dx_1 \triangleq dx_2$  iff

$$x \oplus dx_1 = x \oplus dx_2$$

that is, have same effect when applied.

$\{\{1,2,3,4,5\}\} \ominus \{\{1,1,2,3,4\}\}$  can be represented  
 by  $\{\{5, \underline{1}\}\}$  or by “change **1** through **+4**”, so

$\{\{5, \underline{1}\}\} \triangleq$  “change **1** through **+4**”

# Changes also form a category

- Objects: values of type  $V$
- Arrows: an arrow from  $a$  to  $b$  is a (set of  $\triangle$  changes) going from  $a$  to  $b$

# Derived ops give a category

## Derived ops

$$\mathbf{0}_x = x \ominus x \quad \textit{nil change}$$

$$dx_1 \odot dx_2 = (x_1 \oplus dx_1) \oplus dx_2 \ominus x_1 \quad \textit{change composition}$$

## Derived algebraic equations

$$x \oplus \mathbf{0}_x = x \quad \textit{right unit for } \oplus$$

$$dx \odot \mathbf{0} \triangleq \mathbf{0} \odot dx \triangleq dx \quad \textit{composition unit}$$

$$(dx_1 \odot dx_2) \odot dx_3 \triangleq dx_1 \odot (dx_2 \odot dx_3) \quad \textit{composition associativity}$$

# (Static) Differentiation

- Given a (simply-typed)  $\lambda$ -term  $f$ :

*Derive*

Program  $f$

Derivative  $f'$

- $f'$  is a  $\lambda$ -term, the *derivative* of  $f$
- $f'$  can be optimized further!
- Correctness (proved in Agda):

$$\llbracket f (a \oplus da) \rrbracket = \llbracket f a \oplus \mathbf{Derive}(f) a da \rrbracket$$

# “Derivatives” are non-linear!

- Set  $f' = \mathbf{Derive}(f)$
- $f' a (da \odot db) =$   
 $f' a da \odot f' (a \oplus da) db \neq$   
 $f' a da \odot f' a db$

# Vs calculus

- That's because  $a \oplus da$  can't be approximated with  $a$ , unlike in calculus:
  - changes do not "tend to zero" ("infinitesimal"), they are finite
- Incremental calculi (ours and other ones) are thus closer to the calculus of *finite differences* than the one of *derivatives*.

## ***Vs differential lambda calculus***

- Contrast with linearity in ***differential lambda calculus***:

$$\partial f / \partial x \cdot (dx + dy) = \partial f / \partial x \cdot dx + \partial f / \partial x \cdot dy$$

- You can model  $\partial f / \partial x \cdot dx$  with the substitution  $x \mapsto x \oplus dx$ ... as  $f[x \mapsto x \oplus dx] \ominus f$
- But it cannot be linear substitution!
- We must compute  $f$  on the new value of  $x$ , that is  $x \oplus dx$ , so we substitute everywhere.

- $\llbracket f(a \oplus da) \rrbracket = \llbracket f a \oplus f' a da \rrbracket$
- $\llbracket f(a \oplus da \oplus db) \rrbracket = \llbracket f a \oplus f' a (da \odot db) \rrbracket$
- $\llbracket f a \oplus f' a (da \odot db) \rrbracket = \llbracket f(a \oplus da \oplus db) \rrbracket =$   
 $\llbracket f a \oplus f' a da \oplus f' (a \oplus da) db \rrbracket$

# Derivative examples #1

$$\text{id}_T = \lambda (x : T). x$$

$$\text{id}_T' = \mathbf{Derive}(\text{id}_T) = \lambda (x : T) (dx : \Delta T). dx$$

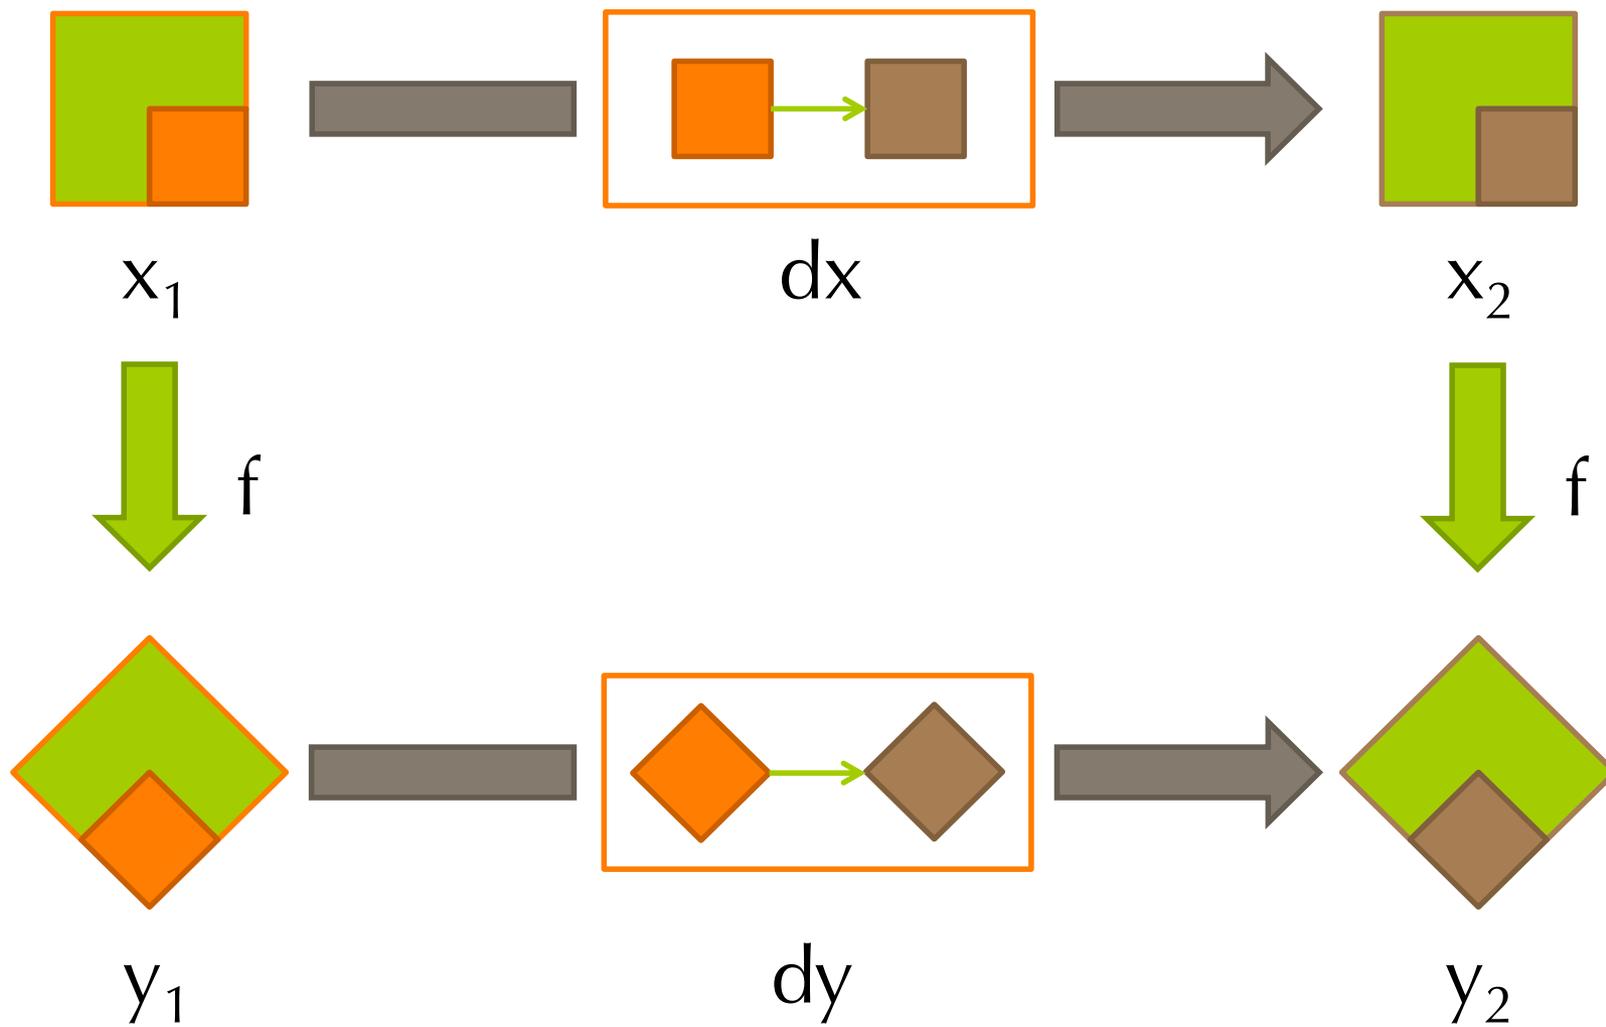

- $\Delta T$ , not  $\Delta x$ 
  - no dependent types
- $\Delta T$  is expanded by **Derive**
- changes ( $dx$ ) are first-class

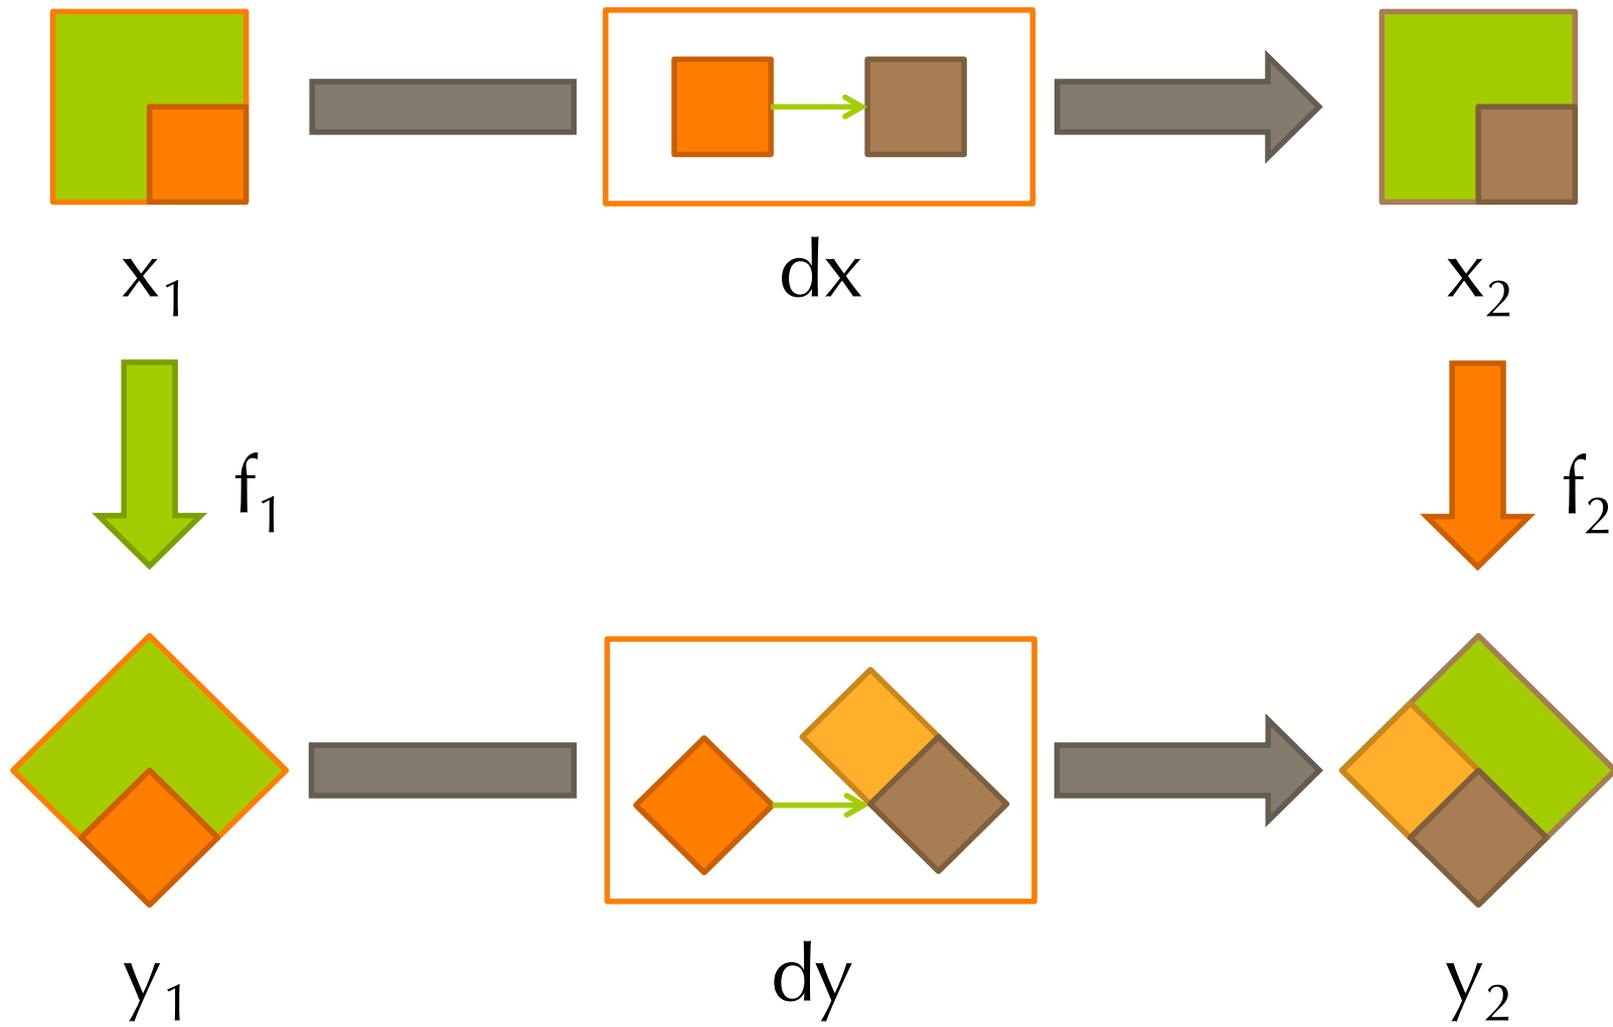

# First-class functions

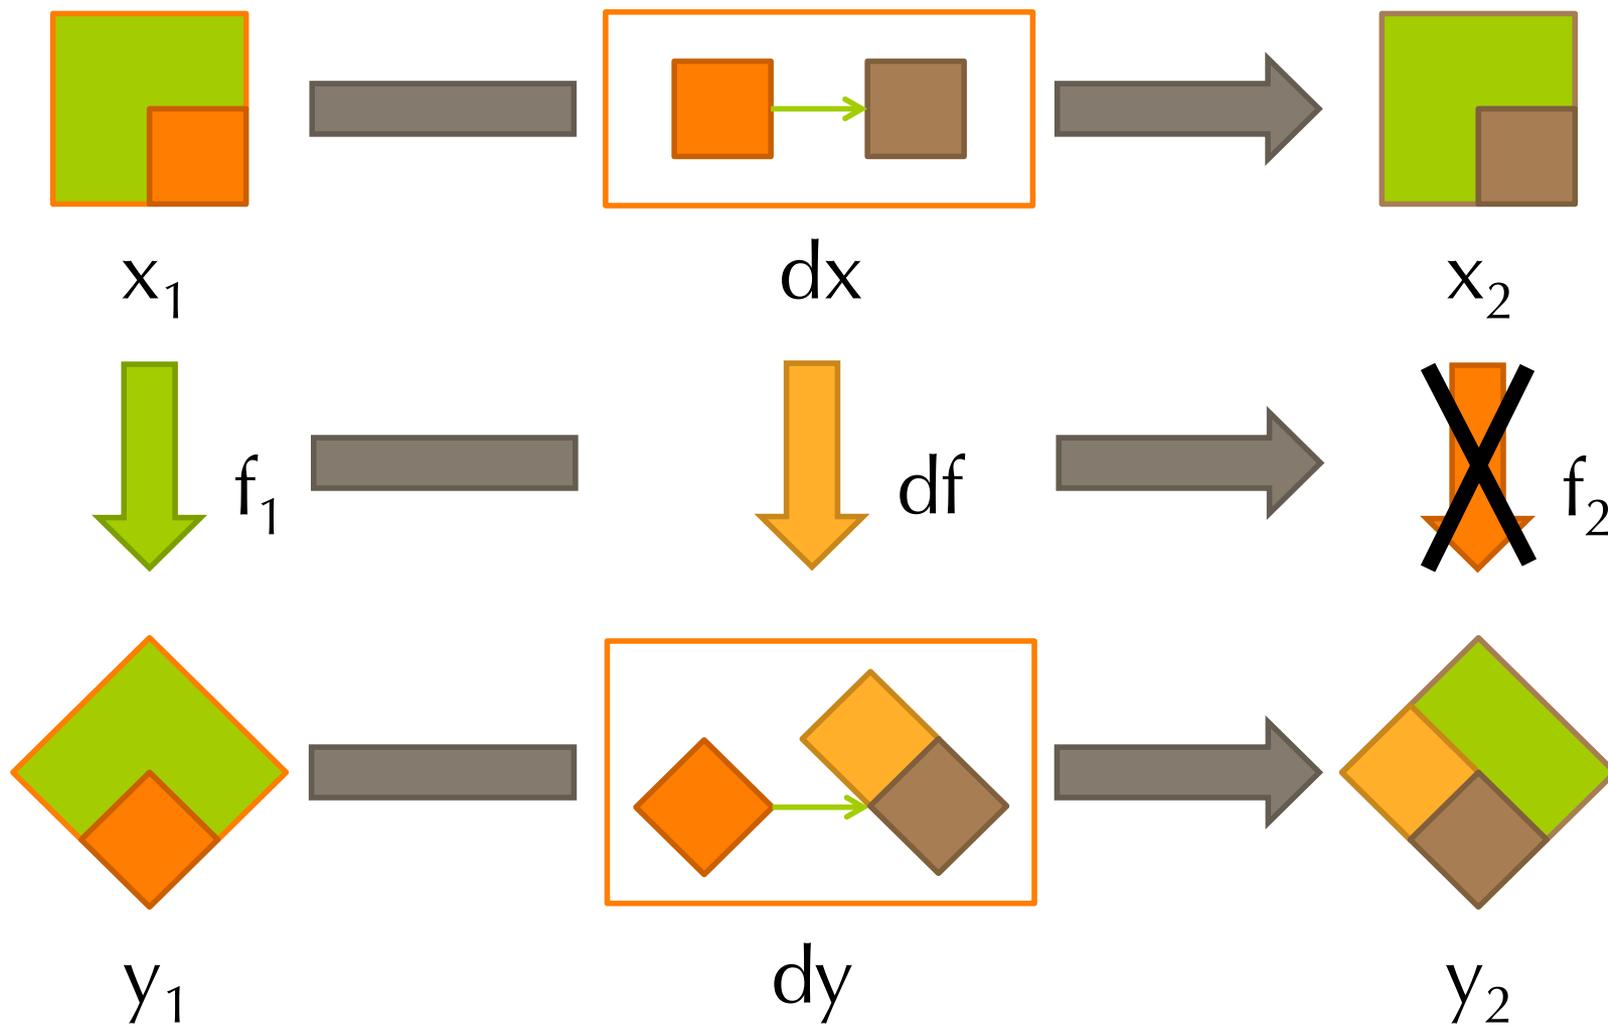

---

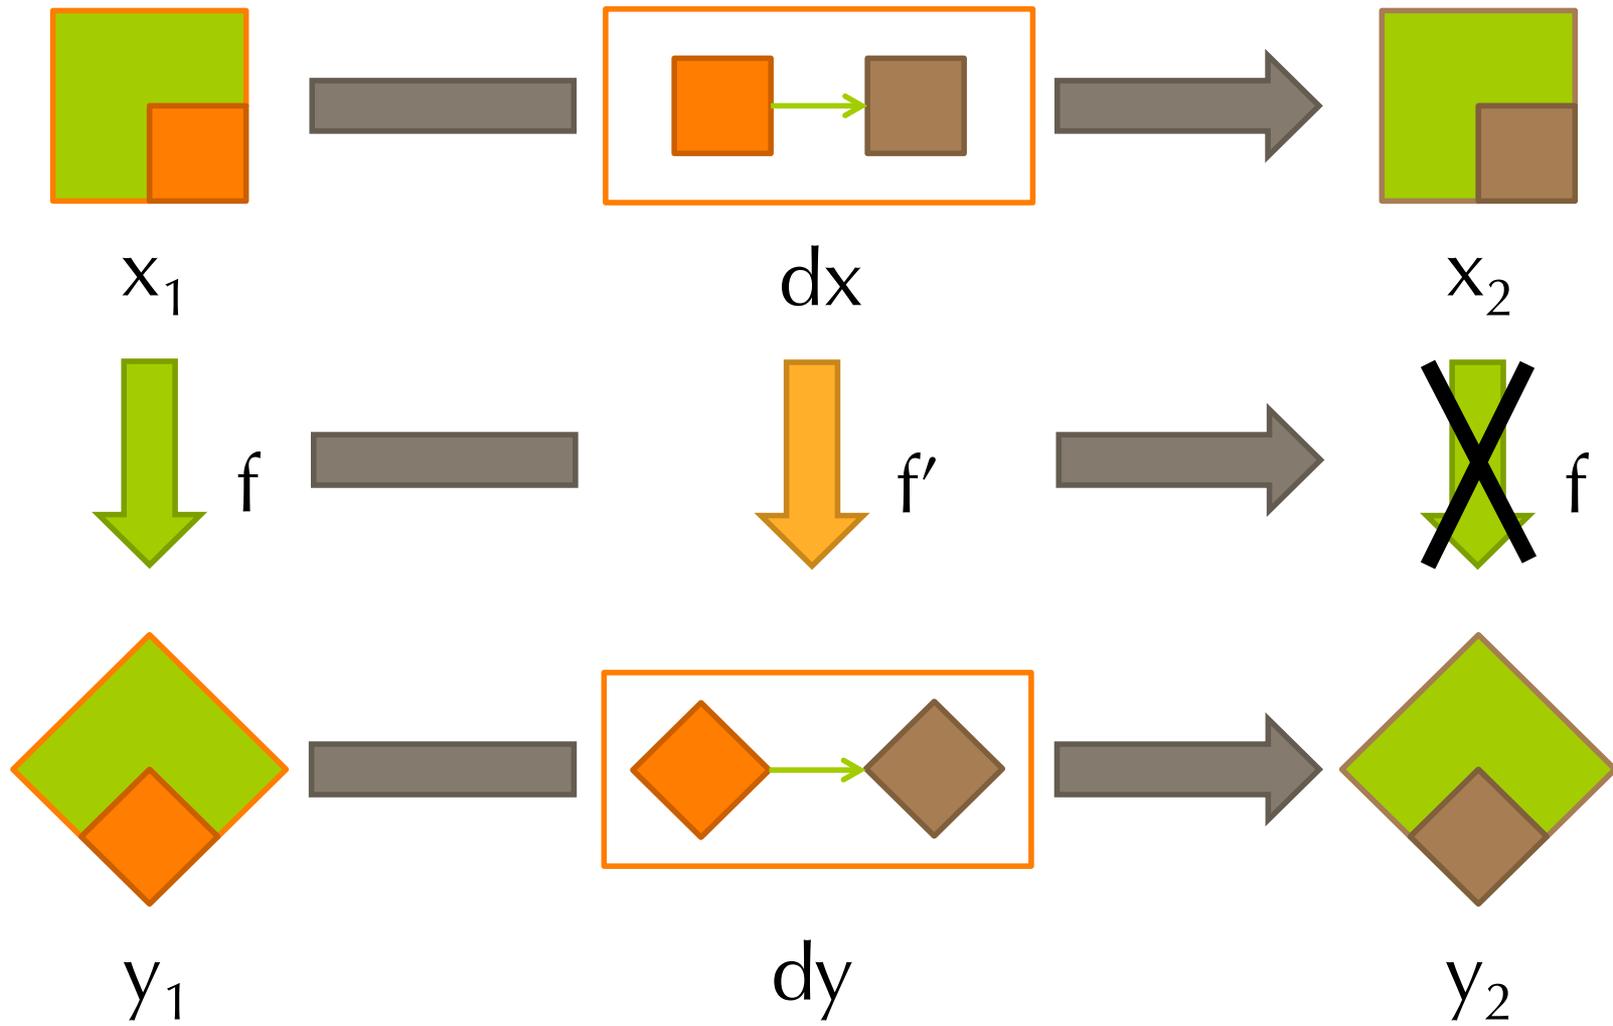

# First-class functions

- Functions are data
- So they can change!
- Concretely, a closure changes if data in its environment changes

# Derivatives $\rightarrow$ function changes

From:

$$f'_{x_1} dx = f_{x_2} \ominus f_{x_1} = y_2 \ominus y_1 = dy$$

to:

$$df_{x_1} dx = f_2_{x_2} \ominus f_1_{x_1} = y_2 \ominus y_1 = dy$$

- Function values change, e.g. because data in closures change!
- Change structure for functions in paper

# Change structure for functions

$$\Delta_{\sigma \rightarrow \tau} = \lambda (f: \llbracket \sigma \rightarrow \tau \rrbracket) \rightarrow \\ \sum_{df : \forall (x : \llbracket \sigma \rrbracket) (dx : \Delta x) \rightarrow \Delta (f x)} \textit{valid} (f, df)$$

## Derivative examples #2

$$\text{id}_T = \lambda (x : T). x$$

$$\text{id}_T' = \mathbf{Derive}(\text{id}_T) = \lambda (x : T) (dx : \Delta T). dx$$

$$\text{app}_{TU} = \lambda (f : T \rightarrow U) (x : T). f x$$

$$\begin{aligned} \text{app}_{TU}' &= \mathbf{Derive}(\text{app}_{TU}) = \\ &\lambda (f : T \rightarrow U) (df : \Delta(T \rightarrow U)) \\ &\quad (x : T) (dx : \Delta T). df x dx \end{aligned}$$

$$\Delta(T \rightarrow U) = T \rightarrow \Delta T \rightarrow \Delta U$$

# Language

$$T ::= \iota \mid T_1 \rightarrow T_2$$

$$t ::=$$

$$s \ t \mid \lambda x^T. t \mid x^T \mid c$$

Base types and constants specified by a language plugin.

# Deriving terms

We require that `Derive` satisfies admissible rule:

$$\frac{\Gamma \vdash t : T}{\Gamma, \Delta\Gamma \vdash \text{Derive}(t) : \Delta T}$$

$$\Gamma, \Delta\Gamma \vdash \text{Derive}(t) : \Delta T$$

$$\Delta\iota = \dots$$

$$\Delta(T_1 \rightarrow T_2) = T_1 \rightarrow \Delta T_1 \rightarrow \Delta T_2$$

# Deriving terms

Propagate changes:

$$\text{Derive}(s \ t) = \text{Derive}(s) \ t \ \text{Derive}(t)$$
$$\text{Derive}(\lambda x. \ t) = \lambda x \ dx. \ \text{Derive}(t)$$

Return changes:

$$\text{Derive}(x) = dx$$

Change of primitives:

$$\text{Derive}(c) = dc$$

# Deriving terms

- The derivative only “follows” the computation propagating changes
- Derivatives of primitives receive inputs and changes, and should compute output changes **efficiently**

# Incrementalizing $\lambda$ -calculi

- **Language plugins** define datatypes and their change structures
- They also define primitives and how to handle them
- Use existing/new research

# Which primitives?

- 1<sup>st</sup>-class functions  $\Rightarrow$  few primitives (e.g. folds) required, other ops (e.g. map) in libraries
- Primitives encapsulate efficiently incrementalizable skeletons

# Example

$f \text{ coll} = \text{fold } (+) \ 0 \ \text{coll}$

$y = f \ x$

$\text{coll}_0 = \{\{1, 1, 2, 3, 4\}\}$

$\text{coll}_1 = \{\{1, 2, 3, 4, 5\}\}$

$\text{dcoll} = \{\{1, 2, 3, 4, 5\}\} \ominus \{\{1, 1, 2, 3, 4\}\} = \{\{5, \underline{1}\}\}$

What about the removal of 1?

# Example

sum s = fold (+) 0 s

y = sum coll

dsum s ds = ... = fold (+) 0 ds

dy = dsum coll dcoll

coll<sub>0</sub> = {{1,2,3,4}}

coll<sub>1</sub> = {{2,3,4,5}}

dcoll = {{2,3,4,5}} ⊖ {{1,2,3,4}} = {{1, 5}}

# Running example & primitives

f coll = fold (+) 0 coll

y = f x

$x_1 = \{\{1, 1, 2, 3, 4\}\}$

$x_2 = \{\{1, 2, 3, 4, 5\}\}$

$dx = \{\{1, 2, 3, 4, 5\}\} \ominus \{\{1, 1, 2, 3, 4\}\} = \{\{5, \underline{1}\}\}$

What about 1, i.e. the removal of 1?

# Running example & primitives

f coll = fold **G** coll      **G** abelian group!

y = f x

x<sub>1</sub> = {{**1**, 1, 2, 3, 4}}

x<sub>2</sub> = {{1, 2, 3, 4, **5**}}

dx = {{1, 2, 3, 4, **5**}} ⊖ {{**1**, 1, 2, 3, 4}} = {{5, 1}}

// if d**G** is the nil change of **G**

df x<sub>1</sub> dx = fold' **G** d**G** x<sub>1</sub> dx = ... = fold **G** dx = 4

dy = df x<sub>1</sub> dx

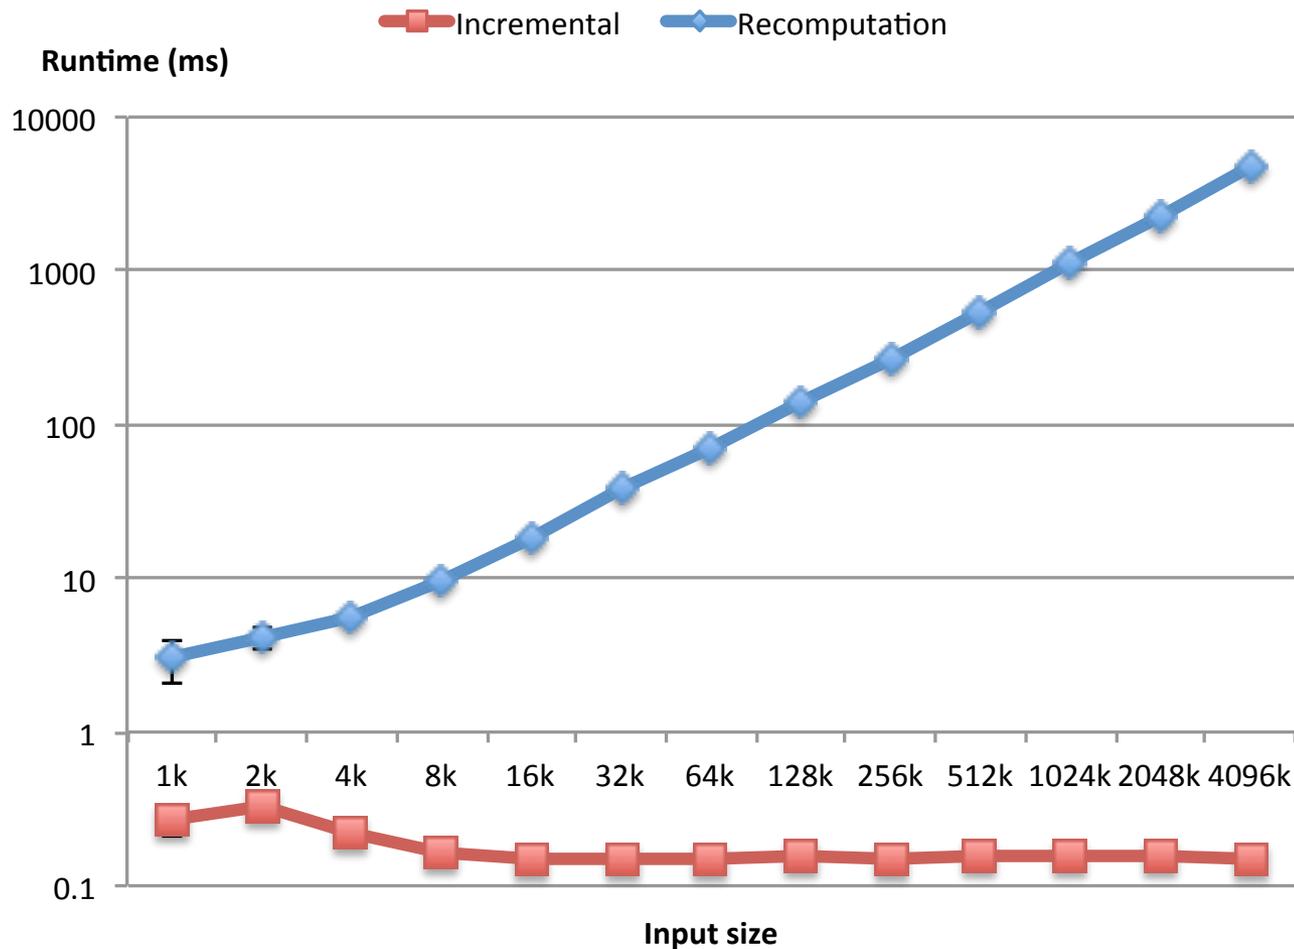

# Caching intermediate results

The derivative reuses results:

$$\text{Derive}(s \ t) = \text{Derive}(s) \ t \ \text{Derive}(t)$$

- Term  $t$  was already computed! We could reuse the result, but we do not save it...
- Right now, if  $t$  is needed, you must recompute it.
- Up to now: focus on cases you don't need it
- Present work: reusing Liu&Teitelbaum [1995]

# Performance case study (based on) MapReduce:

# In the paper...

- Change structure for first-class functions!
- A code transformation for  $\lambda$ -calculi
- A mechanized correctness proof (in Agda, with *denotational semantics & logical relations*)
- Some hints on applying ToC
- Implementation, language plugin with bags and maps, and performance case study in Scala

## A Theory of Changes for Higher-Order Languages Incremental $\lambda$ -Calculus by Static Differentiation

Yufei Cai Paolo G. Giarrusso Tillmann Rendel Klaus Ostermann  
Philippe-Université Marburg

### Abstract

In the context of an expressive computation modelled by a small change to the input, the old result should be updated incrementally instead of recomputing the whole computation. We formalize this intuition through their denotations. A denotational model changes the program's input directly to changes in the program's output. This means that the original program, by means of a program transformer taking programs to their derivatives, which is fully static and automatic, requires first-class functions, and produces derivatives amenable to standard operations.

We prove the program transformer correct in Agda for a small set of simple typed  $\lambda$ -calculi, generalised to both types and positions. A precise analysis specifies what is required to mechanize the chosen properties.

We investigate performance by a case study. We implement in Scala the program transformer, a plugin and explore performance of derivative programs by means of benchmarks.

**Keywords:** Incremental computation, first-class functions, performance, Agda, formalization.

**Categories and Subject Descriptors:** D.3.1 [Programming Techniques]: Application Formalisms; D.3.2 [Programming Techniques]: Language Constructs and Features; D.3.4 [Programming Techniques]: Processors—Optimizers.

### 1. Introduction

Incremental computation has a long-standing history in computer science [21]. Often, a program needs to update its output efficiently in order to cope with changes [22]. Instead of re-evaluating such a program from scratch, one can re-evaluate only the parts that have changed since the last update, which is much faster than the original program, which calculates the sum of all numbers in the collection  $xs$ .

For instance, consider the `sum_of_squares` program, which calculates the sum of all numbers in the collection  $xs$ .

```
sum_of_squares :: [Int] -> Int
sum_of_squares xs = sum $ map (\x -> x * x) xs
```

With `xs = [1..10]` the program is evaluated on `xs`, and we get an output collection (like a list) where elements are allowed to be

reused in some Agda or Java code. If we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before. However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before. However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before.

However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before. However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before.

However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before. However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before.

However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before. However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before.

However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before. However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before.

However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before. However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before.

However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before.

However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before. However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before.

However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before. However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before.

However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before. However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before.

appear more than once (which is not). Now assume that the input  $xs$  changes from `[1..10]` to `[1..11]`, and an `xs` change from `[1..5, 4]` to `[1..2, 3, 5, 7]`. Instead of recomputing `sum_of_squares` from scratch, we could compute it incrementally. For example, a representation of the change to the system from `xs = [1..5, 4]` to `xs' = [1..2, 3, 5, 7]` can be computed as the new result through a function `deriv_of` that takes the old input `xs = [1..5, 4]`, `xs' = [1..2, 3, 5, 7]` and the change `deriv_of` to produce the original change. Thus, it would compute the change `deriv_of xs = [1..5, 4]`, `xs' = [1..2, 3, 5, 7]` and the change `deriv_of` to produce the original change `xs` as well as the updated result `xs'`. We call `deriv_of` the structure of `deriv_of` is a function to the same language as `deriv_of`, accepting and producing changes, which are equal to the value of the language. This means that `deriv_of` is a function to the same language as `deriv_of`, which is similar to our example and its generalization.

To support incremental computation, we define an automatic program transformation that differentiates programs that compute their derivatives. These derivatives are

denoted as `deriv_of` (where `f` is the original program, `deriv_of f` is the derivative of `f`, and `deriv_of f` is the derivative of `f`).

For instance, consider the `sum_of_squares` program, which calculates the sum of all numbers in the collection  $xs$ .

```
sum_of_squares :: [Int] -> Int
sum_of_squares xs = sum $ map (\x -> x * x) xs
```

With `xs = [1..10]` the program is evaluated on `xs`, and we get an output collection (like a list) where elements are allowed to be

reused in some Agda or Java code. If we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before. However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before.

However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before. However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before.

However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before. However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before.

However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before. However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before.

However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before. However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before.

However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before. However, if we use the `sum` function from the `Agda` standard library, the program will be evaluated on `xs` and we will get the same output as before.

# Conclusions

- Incremental computation can give great performance advantages
- Theory of Changes for describing incremental computation
  - maybe applicable to other approaches
- Lots of work to do
  - Lots of avenues for future work — talk to us!

# Further optimizations

- Since we create an incremental program, we can optimize it!
- To avoid computing intermediate results we don't use, this time we transform abstractions to be by-name lambdas.
- We could use absence analysis in the future.
- Further transformations possible.

# Questions?

# Static caching

---

# Static caching

- Based on work of Liu&Teitelbaum [1995]
- Basic idea: remember and save intermediate results of all computations
- **Whenever a *computation* returns a *value***, save the value for future reuse
- Each function returns a tuple:
  - its original return value
  - all intermediate results

# Static caching & CBPV

- What's the correct notion of *computation* and *value*?
  - First attempt: A-normal form
  - Is a partially applied curried function a value?
  - Should we save the result of primitives?
    - Result of pair constructors, introduction forms: not needed, because they create values
    - Result of elimination forms: needed
    - Answer: we should save the result of computations, not of values, and divide primitives accordingly

# Change equivalence

# Change equivalence

- A change can have different but  $\triangleq$  representations, but they should not be distinguished.
- Change operations (the ones in the signature) preserve  $\triangleq$ .
- If a function only accesses changes via operations in the signature, it preserves  $\triangleq$ .
- We'll restrict attention to such functions.

# Restrict attention to $\triangle$ - respecting functions

- We just restrict attention to function with “abstract enough” types
  - Change types must be abstract
- Those functions can only access changes with the change interface ...
- ... so those functions can't distinguish equivalent changes!

# In Ocaml

```
module type Base = sig type v end;;
module type Change =
  functor (B: Base) ->
    sig
      type v = B.v
      type dv (*sealed in structures!*)
      val  $\oplus$ : v -> dv -> v
      val  $\ominus$ : v -> v -> dv
    end;;
```

# In Ocaml

```
module type Change = sig
  type v (*concrete in structures*)
  type dv (*sealed in structures!*)
  val oplus: v -> dv -> v
  val ominus: v -> v -> dv
end;;
```

```
module type ChangeInt
= sig
    include Change with type v =
int
    val plusDeriv :
        v -> dv -> v -> dv -> dv
end;;
```

# In Ocaml

```
module ChangeIntStruct : ChangeInt
= struct
  type v = int
  type dv = int (* sealed! *)
  let oplus v dv = v + dv
  let ominus v2 v1 = v2 - v1
  let plusDeriv x dx y dy = dx +
dy
  end;;
```

# Conjecture on d.o.e.

“D.o.e. ( $\triangleq$ ) implies observational equivalence.”

Open questions:

- must check that functions have “abstract enough” dependent types
- we need a proof of parametricity for the type theory we use
  - we can express the change signature with ML module system, and translate that to System Fomega through techniques by (XXX citation) *F-ing modules* paper

# Understanding our changes

- $\Sigma_{x:V}(\Delta x/\triangle) \cong V \times V$
- $(A \rightarrow B) \times (A \rightarrow B) \cong (A \rightarrow B \times B) \cong A \rightarrow \Sigma_{x:B}(\Delta x/\triangle)$
- $A \rightarrow \Sigma_{x:B}(\Delta x/\triangle) \cong \{ f : \Sigma_{x:A}(\Delta x/\triangle) \rightarrow \Sigma_{x:B}(\Delta x/\triangle) \mid f \text{ is a valid derivative} \}$

# Understanding our semantics

- $\lambda V. \Sigma_{x:V} (\Delta x / \triangle) \cong \lambda V. V \times V$  monad
- Is our semantics related to “just” a standard categorical semantics in the Eilenberg-Moore category of this monad?

# A categorically-inspired semantics

- Claim: it's useful to design the definition of change structures using category theory
- If we do that, we see that semantically
  - $\sum_{V:V} (\Delta V / \cong) \cong V \times V$

# New slides

---

# XXX

- Add extension of ToC to programs through denotational semantics?
- Or just add proof strategy?
- Relate erasure to realizability!

# Change equality: multiple representations

A change can have multiple  $\triangleq$  representations, but they should not be distinguished.

Semantic functions should respect  $\triangleq$ ; that's guaranteed if they only use the change signature.

# Change equivalence (conjecture)

- Thanks to parametricity for abstract types, clients of **Change** can't observe the difference between d.o.e. changes, so d.o.e. changes are *observationally equivalent!*
- We conjecture that all programs we want are valid clients of **Change** & c. (we just didn't check yet).
- We need parametricity for the right language — we conjecture *F-ing modules* is enough.

# Warning

- This presentation (and the paper) uses set theory for “simplicity”
- In fact, our Agda formalization uses *type theory*!
- $\Delta v$  is a dependent type of changes!
- $\Delta v_1$  and  $\Delta v_2$  are disjoint iff  $v_1 \neq v_2$
- (XXX This is needed for the categorical semantics)

- Changes DT for a type T have:
- a source of type T
- a destination of type T
- We have functions from
- (These aren't necessarily computable)
